ECE 661 HW 2

Chad Aeschliman

2008-09-18

1 Problem

The problem is to determine the homography H up to similarity which maps a point or line from a plane in the world to the image plane $\acute{x}=Hx$. This is to be done using two different methods. For the first method, the projective error is first removed followed by the affine error using the provided coordinates of a rectangle and an additional orthogonal line pair. For the second method, five orthogonal line pairs are used to determine the image of the dual degenerate conic \acute{C}^*_{∞} and from this H is obtained directly up to similarity.

2 Solution

2.1 2-Step Method

The corner points of the provided rectangle can be used to obtain two sets of parallel lines (the top/bottom edges and left/right edges). Each set of parallel lines intersect at the image of an ideal point (a vanishing point). Thus the two sets of parallel lines provide two vanishing points. Computing the straight line through these points gives the vanishing line l_v . To correct for the projection distortion, the vanishing line needs to be mapped to $l_{\infty} = [0 \ 0 \ 1]^T$. This is done using the homography

$$H_p = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ l_1 & l_2 & l_3 \end{bmatrix} \tag{1}$$

where $\mathbf{l}_{v} = [l_{1} \ l_{2} \ l_{3}]^{T}$.

The second step is to remove the affine distortion. This is done by exploiting the invariance of cosines computed using the dual degenerate conic C_{∞}^* . In particular, for a pair of lines **l** and **m** which are orthogonal in the scene we have

$$0 = \mathbf{\hat{I}}^T H C_{\infty}^* H^T \mathbf{\hat{m}} \tag{2}$$

$$=\hat{\mathbf{I}}^T \hat{C}_{\infty}^* \hat{\mathbf{m}} \tag{3}$$

where $\hat{\mathbf{l}}$ and $\hat{\mathbf{m}}$ are the image of \mathbf{l} and \mathbf{m} . Note that only an affine homography needs to be determined:

$$H_a = \left[\begin{array}{cc} K & \mathbf{0} \\ \mathbf{0} & 1 \end{array} \right] \tag{4}$$

Because of this C_{∞}^* has the form

$$\hat{C}_{\infty}^* = \begin{bmatrix} S & \mathbf{0} \\ \mathbf{0} & 0 \end{bmatrix}$$
(5)

where $S = KK^T$. Because S has only two degrees of freedom (it is symmetric and homogeneous), two sets of orthogonal lines are required to solve for it. One corner of the supplied rectangle is used for one set of orthogonal lines and the other set is supplied separately. Note that two corners of the rectangle cannot be used because parallel lines differ only in the third element which is ignored when multiplying by C_{∞}^* . Once S is determined, an SVD decomposition is used to determine a suitable K, completing H_a . The overall mapping is given by the product of the individual mappings, $H = H_p H)a$.

2.2 C_{∞}^* Method

The previous method used the properties of C_{∞}^* only to correct for affine distortion, however, it can be used to solve for a general homography up to similarity. Let the homography be defined as

$$H = \begin{bmatrix} K & \mathbf{0} \\ \mathbf{v}^T & 1 \end{bmatrix} \tag{6}$$

Then it is easy to show that

$$\dot{C}_{\infty}^* = HC_{\infty}^* H^T = \begin{bmatrix} KK^T & K\mathbf{v} \\ \mathbf{v}^T K^T & \mathbf{v} \mathbf{v}^T \end{bmatrix}$$
(7)

Assuming that we can solve for \acute{C}^*_{∞} in the image, we can determine H by solving first for the 2×2 matrix K and then solving for \mathbf{v} .

To solve for C_{∞}^* , we first write it in the general form

$$\dot{C}_{\infty}^{*} = \begin{bmatrix} a & 0.5b & 0.5d \\ 0.5b & c & 0.5e \\ 0.5d & 0.5e & f \end{bmatrix}$$
(8)

We know that $\hat{\mathbf{I}}^T \hat{C}_{\infty}^* \hat{\mathbf{m}} = 0$ for images of orthogonal lines \mathbf{I} and \mathbf{m} (from the previous section). Plugging in the general form of \hat{C}_{∞}^* gives an equation of the form $0 = \mathbf{w}^T \mathbf{c}$ where the entries in \mathbf{w} are given in the text and $\mathbf{c} = [a \ b \ c \ d \ e \ f]^T$. Stacking five such constraints in a matrix we are able to solve for \mathbf{c} as the null vector giving \hat{C}_{∞}^* .

2.3 Constructing the Corrected Image

To construct the corrected image, the goal is to set up a grid of evenly spaced points in the world plane with each point representing one pixel in the corrected image and then mapping this grid of points to the image using H. The extents of the grid are determined by mapping the corners of the image plane to the world plane using H^{-1} . The smallest and largest coordinates form the extents of the grid. The spacing of the grid points is chosen to set the resolution of the corrected image and the convention was chosen to preserve the width of the original image with the height adjusting as necessary.

In general a grid point does not map to a particular pixel in the original image so linear interpolation was used.

3 Results

9 pairs of original and corrected images for each method are included at the end after the code.

4 Code

4.1 2 step method

```
#include "cv.h"
#include "highgui.h"
#include <stdio.h>
#include <stdlib.h>
void premap_image (CvMat* invH, IplImage* image, int* new_height, double* scale_factor, double*
    trans_x, double* trans_y);
void map_image(CvMat* H, double scale_factor, double trans_x, double trans_y, IplImage* image,
    IplImage* corrected_image);
// utility function which prints out a matrix
